DETAILED ACTION

Newly submitted claim 40 is directed to an invention that is independent or distinct from the invention originally claimed for the following reasons: claim 40 is directed to a new method of generating soybean seed heterozygous for seed coat color by utilizing herbicide resistant varieties and herbicide application. This method would require a separate search from the methods presently claimed.

Since applicant has received an action on the merits for the originally presented invention, this invention has been constructively elected by original presentation for prosecution on the merits. Accordingly, claim 40 is withdrawn from consideration as being directed to a non-elected invention. See 37 CFR 1.142(b) and MPEP § 821.03.

Claim Rejections - 35 USC § 103

The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

Claims 1-4 and 13 are rejected under 35 U.S.C. 103(a) as being unpatentable over Raque (United States Patent Number 5,859,349) or Raque (United States Patent Number 5,994,621) in view of Koziel et al (United States Patent Number 6,403,865) and Williams.

Raque ('349) teaches a seed mixture of 97% to 99% genetically modified food plant seed and 3% to 1% seed of a variety of the same food plant having a phenotypical difference. Raque further teaches dyeing the seed coats of the seed of the plants having a phenotypical difference to

Art Unit: 1661

facilitate pre-planting identification of the transgenic seed mixture. (See, Column 2, lines 30-35.)

Raque ('349) does not teach natural seed coat color as the phenotypical difference between the seed types. Further, Raque ('349) does not teach specific genetic make-ups or seed coat colors.

Raque ('621) teaches a seed mixture of 90% to 99.999% genetically modified food plant seed and 10% to .001% seed of a variety of the same food plant having a phenotypical difference. Raque also teaches dyeing the seed coats of the seed of the plant having a phenotypical difference to facilitate pre-planting identification of the transgenic seed mixture. (See, Column 2, lines 45-50.)

Raque ('621) does not teach natural seed coat color as the phenotypical difference between seed types. Further, Raque ('621) does not teach specific genetic make-ups or seed coat colors.

Koziel et al. teach the use of seed pigmentation to identify transformed transgenic seeds. Specifically, Koziel et al. altered the phenotype of anthocyanin in natural seed coat color to produce a transformed maize line with pigmented seeds in order to identify the transformed seeds of interest by color. This phenotypical color transformation could be linked with other desirable transgenic traits (*i.e.* two or more genetically modified traits), such as the expression of insecticidal activity in the plant. (*See*, Column 12, lines 19-62.)

Koziel et al. do not teach a specific seed mixture or specific genetic make-ups or seed coat colors.

Art Unit: 1661

Williams teaches different seed coat colors and the genetic make-up of those colors in soybeans.

It would have been obvious to a person of ordinary skill in the art at the time the invention was made to use the teachings of Raque ('349) or Raque ('621) in combination with the teachings of Koziel et al. and Williams to produce a transgenic seed mixture that is identifiable by given percentages of seed coat coloration.

One would be motivated to do this for several reasons. Raque ('349) and Raque ('621) note that dyeing seed coats of phenotypically different seeds is advantageous because it leads to easy pre-planting identification of the transgenic seed mixture. Koziel et al. provide similar motivation to alter the natural phenotype of seed coat color, providing that altered natural seed coat color provides an easy means to identify seeds of interest through rapid visual identification, which in turn results in reduced costs and time in identification of seeds containing particular desirable traits. Finally, Williams provides seed coat color make-ups in soybean, noting which varieties are homozygous and heterozygous, and further teaching that seed coat color differences occur in soybean naturally (*i.e.*, without the time-consuming further steps of dyeing the seed coat or genetically engineering differences in seed coat color pigmentation.)

A person of ordinary skill in the art would have an expectation of success in using a seed mixture of differing phenotypes to identify seeds of interest, as Raque ('349) and Raque ('621) have successfully used seed of differing coloration to identify seed mixtures of interest, and as Koziel et al. has used natural seed coat pigmentation to identify transgenic seeds of interest.

As such, the invention as a whole was *prima facie* obvious to a person of ordinary skill in the art at the time the invention was made.

Art Unit: 1661

Claims 5 through 12 are rejected under 35 U.S.C. 103(a) as being unpatentable over Raque (United States Patent Number 5,859,349) or Raque (United States Patent Number 5,994,621) in view of Koziel et al (United States Patent Number 6,403,865) and Williams, as applied to Claims 1 through 4, above and further in view of Wright et al (United States Patent Number 5,991,025).

The teachings of Raque ('349), Raque ('621), Koziel et al. and Williams are set forth above.

Raque ('349), Raque ('621), Koziel et al. and Williams do not teach determining seed coat color by measuring total light reflectance, such as by NIR spectophotometry.

Wright et al. teach that the use of NIR spectophotometry to analyze constituents of grains, including cell wall content, are known in the art. (*See*, Column 1, lines 25-35.) Seed coat coloration is predicated on the content of carotenoid and other pigments in cell walls.

It would have been obvious to a person of ordinary skill in the art at the time the invention was made to use, as suggested by the teachings of Wright et al., NIR technology to determine differences in seed coat color for any mixed group of seeds of interest to be segregated by seed coat color; all seed coat colors recited in claims 6 through 12 are known in the art (See, e.g., Williams.)

One would be motivated to do this for several reasons. As taught by Wright et al., NIR technology can be integrated into mechanical farm equipment to measure the constituents of a sample. In addition, NIR technology is capable of detecting sophisticated low-level differences in seed coat color for mixed seed samples that do not vary much in pigmentation to the naked eye.

A person of ordinary skill in the art would have an expectation of success in using NIR spectophotometry to determine seed coat color because it was a preferred method in the art for analyzing grain constituents at the time of invention.

As such, the invention as a whole was *prima facie* obvious to a person of ordinary skill in the art at the time the invention was made.

Response to Applicants' Arguments

- 1. The claim rejections under 35 U.S.C. §112 are dropped in response to Applicants' arguments and claim amendments.
- 2. The Examiner has made a new rejection, providing an additional reference that teaches natural seed coat color differences for identification of transgenic seed, as set forth in the rejections under 35 U.S.C. § 103(a) set forth above.

Applicants argue: "[I]t is unreasonable to expect that a reference's recitation of "phenotypical difference" will suggest . . . any one specific phenotypical characteristic . . ."

(Remarks, page 9, second paragraph.) The Examiner agrees. Though the Raque references do not mention natural seed coat color as a phenotypic characteristic of particular interest, this does not teach away from natural seed coat color as a differential phenotypic characteristic because the specific phenotypical characteristics recited in the disclosures are non-exclusive examples.

By dyeing the seed coats for identification purposes, Raque teaches the concept of identifying transgenic seed by observing a small portion of seeds in mixture that differ in coloration. Koziel et al. teach the concept that transgenic seeds can be identified by differences natural seed coat coloration.

Application/Control Number: 10/071,272 Page 7

Art Unit: 1661

3. Applicants state that the arguments regarding Wright et al. and Williams are inapposite.

These references are cited by the examiner to reject specific claim limitations recited by

applicants (i.e., to homozygosity, heterozygosity, specifically claimed genetic soybean seed

makeups and specifically claimed methods of determining seed coat color.) These references are

relevant because they teach specific limitations of the claims of record. The Examiner has

attempted to clarify the rejections under 35 U.S.C. § 103(a) to reflect the relevance of the cited

references.

4. The rejection based on Stroud, Knox and Steyer is dropped in response to Applicants'

arguments.

Allowable Subject Matter

Claims 14 through 18 are allowed.

References Cited

Koziel et al. is provided. The other references found in the rejections of record have previously been made of record in the case.

Future Correspondence

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Wendy C. Haas whose telephone number is (571) 272-0976. The examiner can normally be reached on Monday through Friday 9:00 to 5:30.

Art Unit: 1661
